Title : The Influence of Promedol on the Functional Condition of
Central Nervous Activity and the Stomach in Patients with
Ulcers and Chronic Gastritis

Orig Pub : Tr. Voen.-med. akad., 1957, 74, 273-277

Abstract : During extended use of promedol (I; 16-20 days at 1 ml
of 1% solution, 3 times a day) in 81 patients, normaliza-
tion of the secretory function of the stomach, its acidity
and its motor function occurred in a majority of them.
Also, a normalizing influence of I on the basic process
of the CNS appeared to be expressed. I causes changes of
higher NA of patients, simultaneously influencing sub-
cortical formation [of stimuli]. The effect of I on the

AUTHORS: Mordovin, P. I., Shilov, S. V. SOV/72-58-9-15/20

TITLE: Milling Balls From "Uralit" Mass (Shary iz massy "Uralit")

PERIODICAL: Steklo i keramika, 1958, ⁸Nr 9, pp. 40 - 41 (USSR)

ABSTRACT: Conventional milling balls are usually made of pebble-flint or porcelain. As the production of pebble-flint is very low, balls are produced from flint slabs. Owing to the great wear of these balls undesired admixtures are introduced into the raw materials. In the Engel's plant some insulators are produced from "Uralit" mass with a Al_2O_3 content of at least 75,9%. The milling balls are produced from the same mass and have the following composition: 61,65% of technical alumina of the type G 0 or G 1, 30,92% of grade 1 or 2 Biskul'skaya clay and 7,43% of dolomite. The alumina is used unburned. Furtheron the preparation of the batches and the production of the milling balls is described, which are baked at 1450° for 13,7 hours. Their percentual chemical composition is listed below: SiO_2 not exceeding 18%, TiO_2 not exceeding 0,6%, Fe_2O_3 not exceeding 0,85%,

Card 1/2

Milling Balls From "Uralit" Mass

SOV/72-58-9-15/20

Al_2O_3 at least 75,9%, MgO at least 1,9%, CaO at least 3,5%, alkalies at least 0,55%. The specific weight of Uralite balls is 3-3,2. These balls can also be used in the milling of glaze components. Data resulting from a comparison of working with pebble-flint and with Uralite in various works are given. It can be seen that the usage of Uralite balls results in an increase of the output of the ball mills by a factor of 1,4-2,6 as compared to operation with pebble-flint. The specific consumption of Uralite balls is reduced by a factor of 3-4. The production of Uralite balls is very simple and requires no special equipment. There is 1 table.

TITLE: Using digital computers for calculating losses in blade cascades of
turbomachines *26*

SOURCE: *V.10* Energomashinostroyeniye, no. 8, 1964, 36-37

TOPIC TAGS: turbomachine, turbomachine design, blade cascade *23*

ABSTRACT: This problem is considered: Given a theoretical velocity distribu-
tion along the blade-cascade outline, find the cascade losses. In the course of
developing the computer algorithm, the problem was subdivided into two parts:
(1) Calculation of flow zones (determination of start and finish points) and
(2) Calculation of the boundary layer, losses, and efficiency for all types of flow,
laminary, transitional, and turbulent. The first part was solved by conventional

Card 1/2

L 8456-65
ACCESSION NR: AP4044512

means (alignment charts and curves). The second part was programed into the "Ural" computer; the floating-point mode was selected, and 1,040 commands used. The results of these calculations are compared with experimental data (obtained from static blowdown tests) for 9 blade cascades. Orig. art. has: 8 formulas and 1 table.

Ed.: A. S. Nesterenko; Tech. Ed.: A. S. Trofimenko.

PURPOSE: This popular science booklet is intended for the general reader.

COVERAGE: The booklet describes the physical principles which would govern the operation of a future photon space ship. The weight, pressure, and reaction of light, antimatter, and laws of the theory of relativity are discussed. The foreword is written by N. P. Selivanov, Candidate of Physics and Mathematics. There are 26 references: 24 Soviet (including 1 translation), and

TITLE: Evaluation of the Condenser Capacitance in the
Emitter Circuit of a Transistor in Tuned
Amplifiers

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy,
Radiotekhnika, 1960, Vol. 3, No. 2, pp 287-289

TEXT: The temperature stability of a tuned transistor
amplifier can be increased by connecting a resistance R
in parallel with the capacitance C in the emitter circuit
of the transistor (Fig. 1). The capacitance is usually
determined from:

$$C \geq \frac{5 \div 10}{2\pi f_H R} \quad (1)$$

where f_H is the nominal operating frequency of the device.
The experiments show, however, that if C is determined
from this formula, the amplifiers have a tendency to become
unstable. It is therefore necessary to investigate the effect
of RC on the stability of tuned amplifiers. For this purpose,

Circuit of a Transistor in Tuned Amplifiers

the input and the output resistances of the amplifier are determined. These resistance are expressed by Eqs. (6) and (7). The input resistance can become negative when the inequality defined by Eq. (8) is fulfilled, whereas the output resistance is negative when the condition expressed by Eq. (10) is met. The final expression for the emitter capacitance C is given by:

$$C \geq C_0 = \gamma + \sqrt{\gamma^2 - \lambda} \quad (12) \quad \checkmark$$

where:

$$\gamma = \frac{\tau_{11} + \tau_{21}}{2r_{21}}, \quad \lambda = \frac{1}{\omega^2 r_{21} R}.$$

The quantities τ_{11} , τ_{21} and r_{21} in Eq. (12) are defined on p. 288. Experiments showed that Eq. (12) permits

TEXT: On the mill ЦКБММ-35 (TsKBMM-35) with roll diameter 260 mm comparison tests were made on the forming during rolling of the alloy БТ-1Д (BT-1D), steel 45, and Pb. Data are given on spread, forward flow, ductility, adherence, and slip, obtained during hot rolling with the use of the usual methods. The experience in rolling angles 18.7 x 18, 7 x 5 from steel 45 and alloy BT-1D is briefly described. It is concluded that the grooving of the profile made of alloy BT-1D at rolling temperatures of 850 - 1,100°C may be calculated just as for medium-carbon steel provided that the correction factor of approximately 1.5 for spread of the alloy BT-1D is taken into account. TITLE: Peculiarities of the change of shape of technically pure titanium in hot rolling

SOURCE: Akademiya nauk SSSR. Institut metallurgii. Titan i yego splavy. No. 4, Moscow, 1960. Metallurgiya titana, 171-183

TEXT: Experiments were carried out in a universal hot-rolling mill with ground steel rollers of 260 mm diameter. The power of the main motor of the mill was 55 kW. Since the investigation was concerned not only with lateral spread and forward flow, but also with the deformation at the center which required stopping of the strip in the roller; the specimens were rolled at a speed of 0.18 m/sec. The sizes of the specimens used can be divided into two groups: (1) those of 96, 68, 51, and 34 mm height, the width in each case being 35 mm and (2) those of 34 mm height, the width being 20 and 51 mm. The length of the specimens was 350 mm, apart from the first one, the length of which was 200 mm. The

Peculiarities of the change ...

change in shape of alloy VT-ID was compared with that of the steel 45 and lead. For this purpose, identical specimens were made of the above metals. Two samples of titanium were investigated without reference specimens. Titanium and steel specimens were heated in an electric furnace with carborundum heaters to a temperature of 900°C. The following were studied: (1) Lateral spread in the temperature range 700-1100°C, (2) forward flow, (3) plasticity and (4) contact slip and sticking. In order to determine the zones in which sticking and slip occur, graduation lines, 2.00 ± 0.02 mm apart, were marked on the specimen surfaces with a planing machine. By measuring the distance between the graduation lines in the center of deformation, the elongations in the contact surface of the center of deformation could be determined, and when the latter were known, the occurrence of adhesion or slip could be easily determined. It was found that the alloy VT-ID had a considerably greater lateral spread than the steel 45 in the temperature range 900-1100°C; this fact must be taken into consideration when calibrating the rollers for simple and complex profiles. At 900°C, the above alloy had a high

Card 2/3

plasticity and a low resistance to deformation, which permitted its deformation by pressure to be carried out to a greater extent than that of steel 45. The coefficient of external friction, calculated from the experimental forward flow, was lower in the case of the VT-ID alloy than that of steel 45 and lead. Lateral spread of the alloy VT-ID occurred as the result of intense barrel formation, and transverse deformation of the contact surfaces was either absent or negative. Length of the adhesion zone for the alloy VI-ID was 86-89% of the length of the center of deformation, whereas in the case of steel 45 and lead, it was 24-75% and 0-49%, respectively, for identical sizes of initial strip and reduction in area. This is ascribed to the different lateral spread of the above metals. There are 12 figures, 2 tables and 11 references: 10 Soviet-bloc and 1 non-Soviet-bloc. X

TITLE: Lateral Spreading of Titanium During Hot Rolling

PERIODICAL: Tsvetnyye metally, 1960, No.9, pp.75-77

TEXT: With rapidly increasing production of wrought titanium products, the problem of behaviour of this metal during rolling has become more and more important and the object of the present investigation was to study one aspect of this problem by comparing spreading of titanium during hot rolling with that of steel and lead. The experiments were carried out on a universal rolling mill with polished steel rolls, 260 mm in diameter. The dimensions of the test pieces varied from 99.87 (height) x 33.8 (width) to 34.07 x 50.92. The first series of experiments was carried out at the rolling speed of 0.18 m/sec. The rolling temperature for steel and titanium in most cases was 900°C, some experiments having been carried out between 700 and 1100°C. The results are reproduced in a table on p.75, the letters in the first column denoting the material of the rolled specimen, T standing for titanium, CT for steel and C for lead.

ber of Ti alloys were plotted. The conditions for cold-rolling Ti alloys were also studied and the parameters of rolling, pressure, stress and roll and reeler speeds were determined. The total pressure of the metals on the rolls and the forward and rear stresses in strip rolling were calculated. The authors conclude that in spite of the moderate plasticity exhibited by some of the new high-strength titanium alloys during reduction, high reductions in area are possible in the rolling of strip under stress owing to the favorable influence of the stressed state. Reductions of 20 - 30% depending on the type of alloy, are possible. The alloys in question were IMP2 (IMP2) and IMP3 (IMP3), produced by vacuum arc melting of the alloys AT3(AT3), AT4 and AT8. There are 6 figures and 1 table. ✓

TITLE: Specific pressures in cold rolling of titanium alloys

SOURCE: Tsvetny*ye metally*, no. 7, 1964, 70-72

TOPIC TAGS: titanium aluminum alloy, AT3 alloy, AT4 alloy, AT6 alloy, titanium alloy cold rolling, mean specific rolling pressure, rolling pressure calculation formula, rolling pressure calculation

ABSTRACT: Experiments have been carried out to verify a formula derived by A. I. Tselikov for calculating mean specific pressures in the cold rolling of thin foil from high-strength metals and alloys. A specific feature of the formula is that it takes into account the elastic properties of the metal being rolled. In these experiments, titanium AT-3, AT-4, and AT-6 alloys, containing 2.5—3.5% Al, 3.5—5.0% Al, 5.0—6.5% Al, respectively, and each containing, 0.4—0.9% Cr, 0.25—0.60% Fe, 0.25—0.60% Si, and 0.01% B, in the form of 50- or 75 mm-wide foil varying in thickness from 0.165 to 0.360 mm, were subjected to one-pass rolling under a mean specific

Card 1/2

ACCESSION NR: AP4042349

pressure calculated from the A. I. Tselikov as well as the conventional (Hitchcock) formulas. The experimental data showed that the taking into account of the elastic properties of the material being rolled resulted in a significantly lower calculated value of the mean specific pressure required to produce an identical thickness reduction. The pressure difference varied from 36 to 41% for AT-3 alloy, from 34 to 39% for AT-4 alloy, and from 32 to 38% for AT-6 alloy, increasing generally with the greater initial thickness of the foil. Orig. art. has: 1 figure, 2 tables, and 1 formula.

ABSTRACT:
Acceleration is a factor which has a deleterious effect on the organism.
The data thus far indicate that accelerations can cause shifts in the func-
tional state of a number of systems (nervous, cardiovascular, digestive,
etc.). From this it can be speculated that destruction of various systems
the organism can lead to changes in immunity. However, the problem of
effect of acceleration on immunoreactivity has been little studied.

ABSTRACT:

Prolonged spaceflights require that man remain in a closed environment with an altered medium under the influence of a series of unfavorable spaceflight factors. In sealed-chamber experiments with human subjects, during which certain spaceflight factors were simulated along with various work and rest schedules, in addition to physiological, psychological, and clinical observations, special attention was given to the study of the microflora of the medium, and the automicroflora and immunological reactivity of the human organism.

✓ Ferrous sulfide and hydrogen sulfide in the bottom sediments of the northwestern parts of the Pacific Ocean

E. A. Ostroumov and V. M. Shilov. *Doklady Akad. Nauk S.S.S.R.* 106, 501-4 (1986). Especially in the bottom sediments of the Kurile Islands-Kamchatka trench, and near the Aleutian Islands, oxidation-reduction conditions are observed similar to those previously discussed from the sediments of the Black and the Caspian Sea. A considerable reduction of sulfates to sulfides and the evolution of free H_2S occurs, and hydrotroilite is pptd. in diatomaceous clays. The upper layers of the sulfide-contg. sediments are usually oxidized with a br wn color, the cores are deep bluish or greenish black. Curves of the S contents of the dry material, plotted vs. the depth of the bottom sediments, are given. The material was taken from deep-sea drilling cores. The S contents vary between 0.0001 and 0.1%; in some of the layers the S content changes rather periodically, evidently as a function of the org. material present (up to 1.2% C was detd.). In deeper horizons the hydrotroilite is changed to spherulitic marcasite, FeS_2 . In sediments of the Kurile Islands-Kamchatka trench, enrichment in Fe^{++} is observed near the contact of the oxidized and reduced zones. Evidently, a migration of Fe^{++} occurs from the reduced zones to these contacts. In these, Fe^{++} is chemically bound in the diatomaceous silica gels forming Fe silicates, analogous to similar reactions in swamps. Free H_2S was observed in very few of the sediments, while hydrotroilite is everywhere present in the reduced horizons. The pH conditions in the oxidizing medium correspond to about 6.7 or 6.8, while in the reducing horizons 7.2, 7.5, and even 8.0 have occurred.

Cenozoic Volcanism of Southern Sakhalin (Kaynozoytskiy vulkanizm Yuzhnogo Sakhalina)

PERIODICAL:

Byulleten' Moskovskogo Obshchestva Ispytateley Prirody, Otdel Geologicheskoy, 1957, # 6, pp 137-138 (USSR)

ABSTRACT:

Three phases of effusive volcanism took place on the territory of South Sakhalin during the Cenozoic era. The first phase began at the end of the Oligocene epoch, and the main manifestation of volcanic activity occurred in the Lower-Miocene epoch. The second phase of volcanic activity manifested itself during the Middle-Miocene epoch. The third phase began at the end of the Lower-Pliocene epoch, and the main manifestations of volcanic activity occurred in the Upper-Pliocene epoch.

Manifestations of Tertiary volcanism in South Sakhalin proceeded on the general background of geosynclinal development. The centers of eruptions were located in the western side of the Western-Sakhalin anticlinorium.

TITLE: On the Problem of Miocenic Volcanogenic Formations of South Sakhalin (K voprosu o miotsenovykh vulkanogennykh formatsiyakh Yuzhnogo Sakhalina)

PERIODICAL: Doklady Akademii nauk SSSR, 1957, Vol. 114, Nr 4, pp. 873-875 (USSR)

ABSTRACT: The volcanogenic material is rather widely distributed here among the tertiary deposits. Its great quantity in the Arkay- and Chekhov suite is especially striking. The formation of both was caused by the occurrence of two different phases of volcanic activity. The products of the first phase are distributed along the whole Western banks of South Sakhalin. The Arkay suite itself is only known in the Southern part of this area. This suite is assumed to form more towards the North together with an other a decomposed volcanic complex: the Khoyndzhi-suite. It is the author's opinion that this applied only to the Kransogorsk district. The products of the second phase (Chekhov-suite) are less widely distributed than the analogous ones of the first phase. They are separated from the latter by thick normal sedimentary formations of the Kholmskaya and partly of the Nevel'skaya suites.

Card 1/4

On the Problem of Miocenic Volcanogenic Formations of South Sakhalin 20-114-4-53/63

the first and second phase are enumerated (figure 1). They stood in an approximately straight line and formed from the paleogeographical point of view island garlands. From the petrographic point of view the eruption products of the first phase are chiefly pyroxenic, rare hornblende andesites and dazites. In the second phase they are more basic and completely represented by basalts. Finally it has to be mentioned that the enumerated volcanogenic masses have scarcely a stratigraphic independence. Their lithological composition is too unstable and their thickness not sufficient. They are therefore considered to be volcanogenic facies of other suites.

TITLE: Some Experimental Data Concerning the Thermal Influence Exerted by Dolerites on the Mineral Coals that Contain Them in South Sakhalin (Nekotoryye eksperimental'nyye dannyye o termal'nom vozdeystvii doleritov na vmeshchayushchiye ikh kamennyye ugli na Yuzhnom Sakhaline)

PERIODICAL: Doklady AN SSSR, 1957, Vol. 115, Nr 6, pp. 1185 - 1188 (USSR)

ABSTRACT: From the temperature which develop at the contact of the intrusive bodies with the rocks containing them, one can judge on the formation temperatures of the intrusive rocks themselves. The correct conceptions on this fact are necessary for an understanding of the processes taking place in this connection and of their influence upon the rocks containing them as well as on the formation of the ore-deposit. In recent volcanic phenomena it may be seen that the solidification of lava, which may be equated with the formation of effusive rocks, takes place at 700 - 800°C. The very high temperature of lava (1100 - 1120°C) is no doubt far from the magma-temperature within the earth's crust. In the same manner the lava-tempera-

Card 1/4

20-6-36/48

Some Experimental Data Concerning the Thermal Influence Exerted by Dolerites on the Mineral Coals that Contain Them in South Sakhalin

in a distance of 2,5 m from it that the capability of sintering is regained, but it does not even in a 20 m distance attain the initial value "20". Coals which are only under the influence of hot gases show a lower degree of metamorphosing. The method of imitating the above-mentioned processes is described. From table 2 may be seen that during 1 hour heating a coke that is analogous to natural coke develops at a rather high temperature (800°C). The curve from a 4 - 8 hours heating shows that a similar coke also develops at lower temperatures (700°C), when the heating lasts accordingly longer. This should also be possible at still lower temperatures. The extension of the heating time is limited, however, since it is known that at 500°C only semicoke develops. The minimum temperature has to be sought between 500 and 700°C and will supposedly lie near 600°C. This temperature is supposed to have prevailed at the contact of the mineral coal with magmatic melts. The solidification-temperature and the formation-temperature of the dolerites respectively probably lay deeper, but not below 550°C. There are 2 figures, 2 tables and 2 Slavic reference.

TITLE: Some Data on the Volcanism of the Middle Miocene Epoch in Southern Sakhalin - the Chekhov Region (Nekotoryye dannyye o srednemiootsenovom vulkanizme Tushnogo Sakhalina - Chekhovskiy rayon)

PERIODICAL: Izvestiya Akademii nauk SSSR, Seriya geologicheskaya, 1958 Nr 12, pp 9-17 (USSR)

ABSTRACT: In the Middle-Miocene epoch, volcanic action in the southern part of Sakhalin island occurred only locally and volcanogenous deposits were found in only a few places. Near the town of Chekhov, these deposits were segregated as an independent stratigraphic unit, the Chekhov suite, conforming to and overlying the Nevel'sk suite. As a result of detailed studies of this suite, of its magnitude and lithological composition, the author comes to the conclusion that the Chekhov suite is only the volcanogenous facies of the Nevel'sk suite.

TITLE: New Data Concerning the Pliocenic Volcanism of South Sakhalin
(Novyye dannyye o pliotsenovom vulkanizme Yuzhnogo Sakhalina)

PERIODICAL: Doklady AN SSSR, 1958, Vol. 118, Nr 1, pp. 174-176 (USSR)

ABSTRACT: Volcanic Pliocene-rocks are most developed and varied in the north western part of South Sakhalin and known as Lamanonskiy massif. On the basis of his investigations the author corrects the original conceptions. Thus he disproves the opinion on 3 phases of volcanic activity. There was only one. The upper part of the Maruyamskaya suite are not Upper-, but Lower-Pliocenic. The beginning of volcanic activity must also be classified with this period. The main part, however, takes place in the second half of the Pliocene. The great variety of types of volcanic products was caused by the evolution of magma in the magma reservoir. Numerous streams of lava, possibly small blankets, seam-like deposits dikes and more seldom basalt-tuffs form the major part of these products. They represent a kind of fairly thick (up to 300 m) blanket on the washed-out surface of the Maruyamskaya suite and of other older Tertiary/suites. The formation of andesite- and dacite-extrusions is connected with the last stages of volcanic activity. At present they form regular conical peaks which are

From these data follows the age of the blanket formations which are older than the period of folding. This circumstance makes the assumption of a special period of folding which is supposed to have partially folded the blanket formations after the general folding unnecessary. As far as a normal sedimentation took place beside the volcanic activity, it would be more correct to consider the Pliocenic volcanic formations only as a volcano-genic facies of the upper part of the Maruyamskaya suite, instead of making them an independent stratigraphic unit.
